

ABSTRACT OF THE DISCLOSURE

A digital camera reduces the possibility that a user's release operation is disabled and performs photographing operations at the appropriate times. The digital camera (1) can load a memory card (40a) and a magnetic disk card (40b) as a plurality of recording media, wherein a CPU (17) can independently make accesses to the memory card (40a) and the magnetic disk card (40b). The CPU (17) performs a plurality of tasks in parallel, whereby a captured image is recorded on either one of the memory card (40a) and the magnetic disk card (40b) while predetermined processing is performed on the other. In such a configuration, a captured image which is stored in image memory (21) through a photographing operation can be recorded at an early stage on one of the recording media. This enables continuous photographing and the like even in such a condition that recording on a recording medium which is selected as a subject of recording is not allowed.
